

Biodiversity Project

Dave Melillo

data in **species_info.csv**.

- The species_info.csv had 4 fields
 - Category
 - Scientific name
 - Common_names
 - Conservation_status
- Observations
 - ~92% of the species had a blank value in the conservation_status field, meaning that no intervention was recommended
 - Birds and Mammals were the most likely species to be endangered when compared to the rest of the categories in the sample.

significance calculations for endangered status between different categories of species

- To understand how the endangered status fluctuates between species we created a pivot table with three measures
 - # not protected
 - # protected
 - Percent protected
- From this pivot table we were able to run a chi squared test
 - The purpose of the test is to evaluate how likely it is that the null hypothesis is true, given the observations
 - Using the chi squared test, we found that there is no significant difference between the endangered status between mammals and birds, while there was a significant difference between mammals and reptiles

Recommendation

- Based on our significance calculations, more time should be invested in conserving birds and mammals, as they are much more likely to be endangered when compared to reptiles, fish, amphibians and various plant categories.

sample size determination for the foot and mouth disease study

- First we had to determine the “Minimum Detectable Effect” expressed as
 - $\text{minimum_detectable_effect} = 100 * 0.05 / 0.15$
- Then we used the result of the minimum detectable effect (~33%) at www.optimizely.com with a 15% baseline conversion rate to get 520
